11   Relation between Shieh's delta and Cohen's delta

12   **Cohen's** δ is the difference between both groups means, divided by a pooled error

13   term:

$$\delta_{Cohen} = \frac{\mu_1 - \mu_2}{\sqrt{\frac{(n_1-1)\times\sigma_1^2 + (n_2-1)\times\sigma_2^2}{n_1+n_2-2}}} \tag{1}$$

14   **Shieh's** δ is the difference between both groups means, divided by an unpooled error

15   term (Shieh, 2013):

$$\delta_{Shieh} = \frac{\mu_1 - \mu_2}{\sqrt{\frac{\sigma_1^2}{n_1/N} + \frac{\sigma_2^2}{n_2/N}}} \tag{2}$$

16   Unlike the classical Cohen's δ, Shieh's δ depends on the sample size ratio (i.e. $\frac{n_1}{n_2}$ that I

17   will call later nratio). For the same amount of differences between two means, same standard

18   deviations and σ-ratio, Shieh's δ will vary as a function of the nratio. Shieh's δ can therefore

19   be expressed as a function of the nratio:

$$\delta_{Shieh} = \frac{(\mu_1 - \mu_2) \times \sqrt{nratio}}{(nratio + 1) \times \hat{\sigma}}, \hat{\sigma} = \sqrt{(1 - \frac{n_1}{N}) \times \sigma_1^2 + (1 - \frac{n_2}{N}) \times \sigma_2^2}. \tag{3}$$

20   To illustrate the relation between Shieh's δ and the nratio, we can calculate the

21   parameter across a range of nratio. We will first study the Shieh's δ (and its relation with

22   Cohen's δ) when variances are equal between groups. We will then go through the relation

23   when variances are unequal between groups.

24   **When variances are equal between groups**

25   As a first example, in Figure 1, Cohen's δ and Shieh's δ are calculated for different

26   configurations where the observed mean difference $(\mu_1 - \mu_2)$ is 1, the total sample size is 200

27 and standard deviations σ_1 and σ_2 both equals 2.

28   First, when sample sizes are equal across groups, one can observe that Shieh's δ is half

29 of the value of Cohen's δ. Shieh's δ equals 0.25 when nratio is 1, and Cohen's δ equals 0.50:

$$\delta_{Shieh,n_1=n_2} = \frac{\delta_{Cohen,n_1=n_2}}{2} \leftrightarrow \delta_{Shieh,n_1=n_2} = \frac{\mu_1 - \mu_2}{2 \times \hat{\sigma}} \qquad (4)$$

30   Note that when variances are equal between groups, Cohen's δ is constant whatever

31 groupe sample sizes are equal or not (i.e. Cohen's $\delta_{n1=n2}$ = Cohen's $\delta_{n1\neq n2}$). This equality

32 will no longer be true when variances are unequal between groups. We use therefore

33 $\delta_{Cohen,n_1=n_2}$ in Formula 4, in order that equality is still applicable when variances are

34 unequal between groups (see later).

35   Moreover, when both sample sizes are equal between groups, Shieh's δ achieves its

36 maximum value. When plotting both parameters against the log of the nratio, one can more

37 easily observe that the Shieh's δ departs symmetrically from it's maximum value as long as

38 the nratio moves away from 1 (i.e. when log(nratio) = 0; see Figure 2).

39   When variances are equal between groups, $\hat{\sigma}$ will be the same for all nratio

40 ($\hat{\sigma} = \sigma_1 = \sigma_2$; i.e. $\hat{\sigma}$ in Figure 3 = $\hat{\sigma}$ in Figure 4), one can deduce that the relation between

41 Shieh's δ value when nratio=1 and its value for all other nratio can be expressed as follows:

$$\delta_{Shieh,n_1=n_2} = \delta_{Shieh} \times \frac{\frac{\mu_1-\mu_2}{2\times\hat{\sigma}}}{\frac{(\mu_1-\mu_2)\times\sqrt{nratio}}{(nratio+1)\times\hat{\sigma}}} \leftrightarrow \delta_{Shieh,n_1=n_2} = \delta_{Shieh} \times \frac{nratio+1}{2\times\sqrt{nratio}} \qquad (5)$$

42   Finally, because of formula 4 and because we know that Cohen's δ is constant for all

43 nratio, when variances are equal between groups, one can conclude that the relation between

44 Cohen's δ and Shieh's δ can be expressed as following:

$$\delta_{Cohen} = \delta_{Shieh} \times \frac{nratio + 1}{\sqrt{(nratio)}} \tag{6}$$

45   This relations remains true as long as variances are equal between groups.

When variances are unequal between groups

47   In Figure 3, Cohen's δ and Shieh's δ are calculated for different configurations where

48   the observed mean difference $(\mu_1 - \mu_2)$ is 1, the total sample size is 200 and standard

49   deviations σ_1 and σ_2 are respectively 4 and 3 (left) or 3 and 4 (right). As one can see, when

50   variances are unequal between groups, Cohen's δ no longer remains constant for all nratio.

51   Once again, it is easier to study the influence of the nratio on both parameters when

52   plotting them against the log of the nratio, as done in Figure 4. The way the standard error

53   term is computed in Cohen's δ (see formula 1) implies that all samples are considered as

54   issued from a common population variance (hence the assumption of homoscedasticity).

55   When there is heteroscedasticity, if the larger variance is associated with the larger sample

56   size (i.e. the colored parts on both plots in Figure 4), the error term is overestimated and

57   therefore, the Cohen's δ is decreased. The smallest value is achieved when the sample size of

58   the group associated with the largest variance equals n-1=199 (i.e. when one gives the

59   largest weight to the largest standard deviation). On the other side, if the larger variance is

60   associated with the smaller sample size (i.e. the non-colored parts of both plots), the error

61   term is underestimated and therefore, the Cohen's δ is increased. The largest value is

62   achieved when the sample size of the group associated with the largest variance equals 1

63   (i.e. when one gives the largest weight to the smallest standard deviation).

64   Unlike Cohen's δ, Shieh's δ is not influenced by the correlation between the sample size

65   and the standard deviation.

66   While it remains true that when $n_1 = n_2$, the Cohen's δ is exactly as twice as large as

⁶⁷ Shieh's δ (Shieh's δ equals 0.25 and Cohen's δ equals 0.50), the maximum Shieh's δ value is

⁶⁸ no longer when the nratio equals 1 (i.e the log of the nratio equals 0). Moreover, Shieh's δ no

⁶⁹ longer departs symmetrically from it's maximum value as a function of the nratio. This is

⁷⁰ due to the fact that $\hat{\sigma}$ will vary a function of the nratio (and will therefore be different for all

⁷¹ configurations presented in Figure 4): as shown in formula 3, one gives more weight to the

⁷² standard deviation associated with the smallest group. For this reason, the maximum

⁷³ Shieh's δ is always achieved when there is a positive correlation between variances and

⁷⁴ sample sizes (i.e. we give more weight to the smallest standard deviation, associated with the

⁷⁵ smallest group) and the more unequal the variances, the further from 1 the nratio associated

⁷⁶ with the maximum , as illustrated in Figure 5.

⁷⁷ As a consequence of different $\hat{\sigma}$ for all nratio's, the relation between Shieh's δ value

⁷⁸ when nratio=1 and its value for all other nratio cannot be as simplifed as it was when

⁷⁹ variances were equal:

$$\delta_{Shieh,n_1=n_2} = \delta_{Shieh} \times \frac{\frac{\mu_1-\mu_2}{2\times\sigma_{(n_1=n_2)}}}{\frac{(\mu_1-\mu_2)\times\sqrt{nratio}}{(nratio+1)\times\sigma_{(n_1\neq n_2)}}} \leftrightarrow \delta_{Shieh,n_1=n_2} = \delta_{Shieh} \times \frac{(nratio+1)\times\sigma_{n_1\neq n_2}}{2\times\sigma_{n_1=n_2}\times\sqrt{nratio}} \quad (7)$$

⁸⁰ With

$$\sigma_{n_1=n_2} = \sqrt{\frac{\sigma_1^2+\sigma_2^2}{2}}$$

⁸¹ and

$$\sigma_{n_1\neq n_2} = \sqrt{(1-\frac{n_1}{N})\times\sigma_1^2 + (1-\frac{n_2}{N})\times\sigma_2^2}$$

⁸² Finally, because of formula 4, one can conclude that the relation between the Cohen's δ

⁸³ we would obtain if sample sizes were equal between groups and Shieh's δ can be expressed as

⁸⁴ following:

$$\delta_{Cohen} = \delta_{Shieh} \times \frac{(nratio + 1) \times \sigma_{n_1 \neq n_2}}{\sigma_{n_1 = n_2} \times \sqrt{nratio}} \tag{8}$$

85   Formula 8 gives us the general relation between Shieh's δ and Cohen's δ,applicable
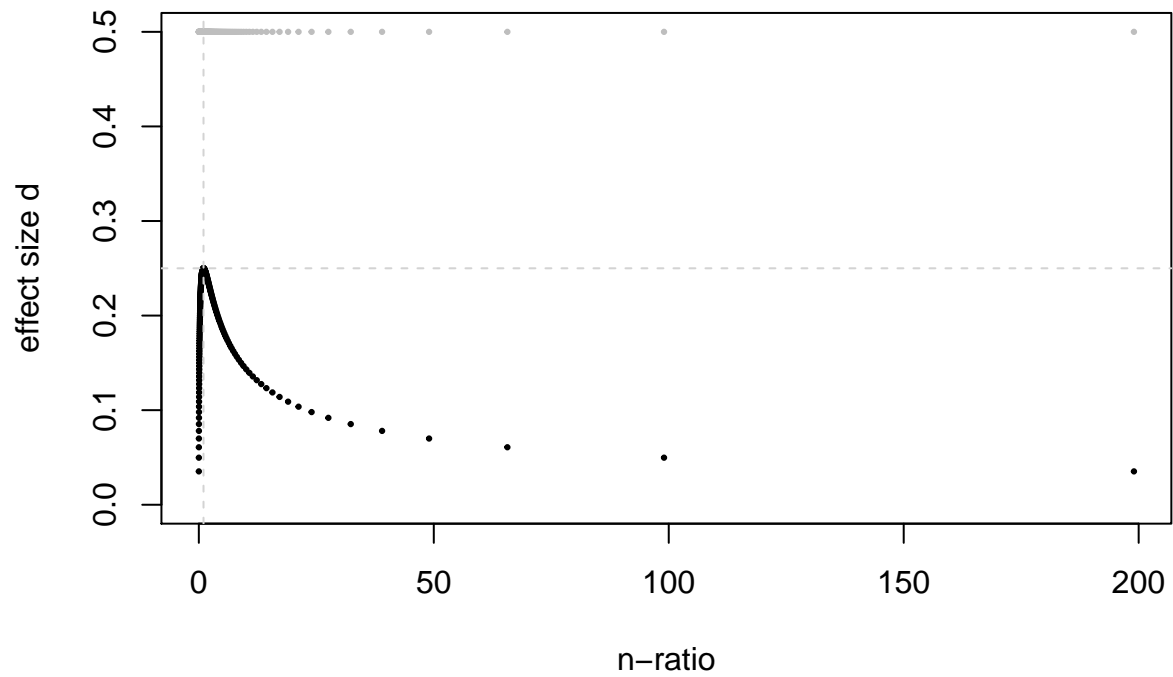

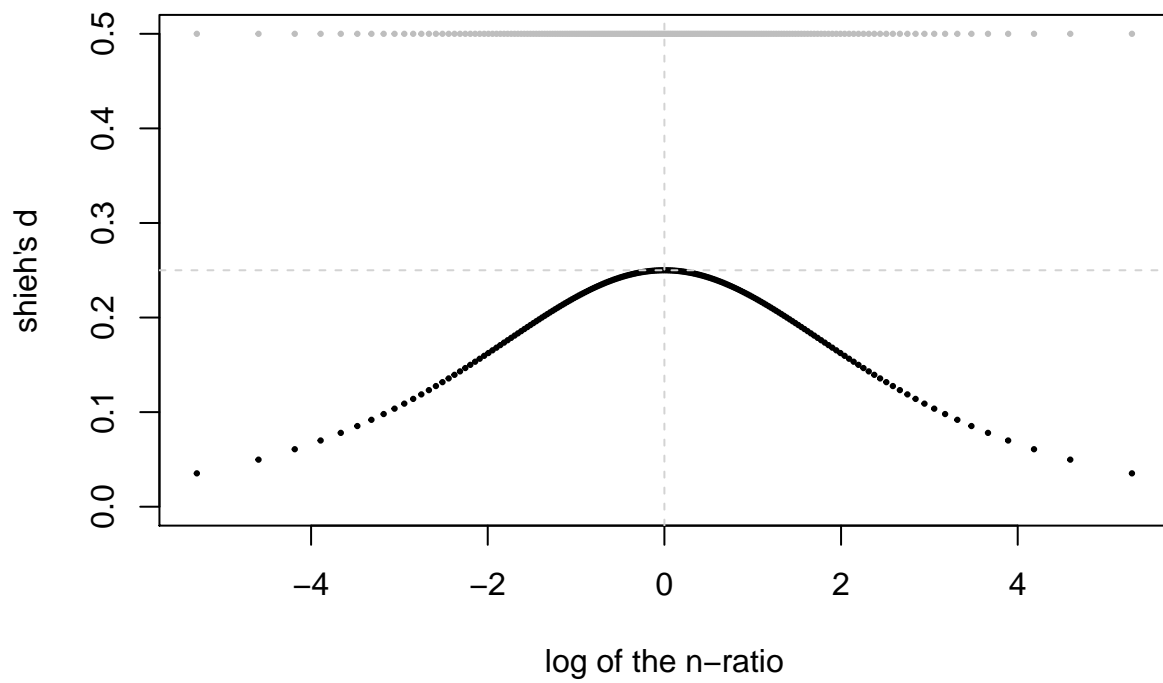

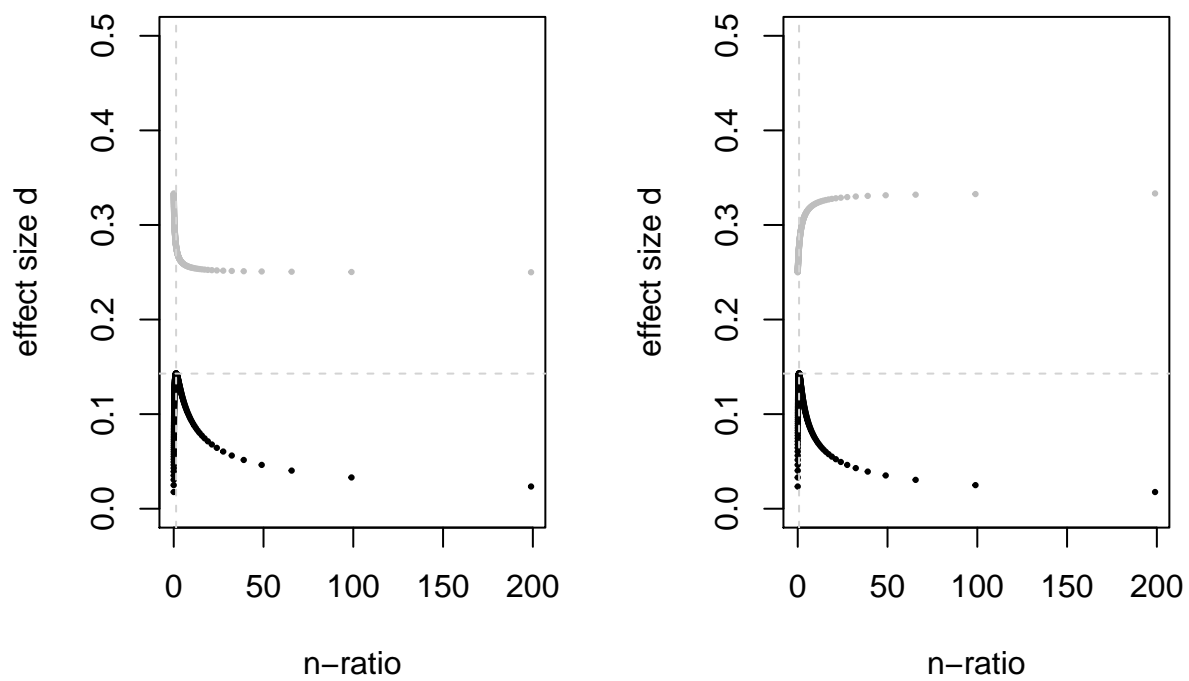

86 whatever variances are equal between groups or not.
